RESEARCH QUESTION

How does a seven win-streak create tension without making failure feel arbitrary?

Scope

This case examines streak pressure, reward uncertainty, the 30-minute retry gate, and fairness perceptions. It uses no internal Playrix data

rules

- 01 Win 7 match-3 levels in a row
- 02 100 players compete in one event group with time limit
- 03 The final reward is divided among the winners (amount of reward depends on them)
- 04 A loss triggers a 30-minute wait before retrying
- 05 The event opens at level 65 and lasts 24 hours

Event loop and failure path

A win advances the streak. A loss pauses the next attempt, needs to start after 30 mins

Design reading

The event turns ordinary levels into a high-stakes sequence. Pressure rises because one loss interrupts progress and time is limited.

Seven wins amplify small differences in level success

$$P(\text{streak}) = p^7$$

If 100 players each make one comparable attempt, the expected number of winners is approximately $100 \times p^7$.

Why it matters

A modest change in level win rate can produce a much larger change in streak completion.

Values are illustrative, not Playrix statistics.

The emotional value of each win increases

from 100 players to 19 in 6 levels

Later wins can increase booster use, attention, and frustration after a loss

Four fairness hypotheses

The event can feel fair only when effort, difficulty, and reward remain understandable.

01 **Level difficulty may vary within a streak**

A hard level near step 7 can feel more punishing than the same level at step 1 (levels hardness depends on user's level)

02 **Players may have unequal success rates**

A shared group can contain players with different skill, boosters, and level difficulty

03 **The final payout is uncertain**

More winners reduce each winner's share, so success does not guarantee a fixed reward

04 **The retry gate adds loss cost**

A 30-minute wait can turn a gameplay failure into a session interruption

Evidence needed: streak funnel, loss step, assigned level difficulty, booster use, retry rate, and reward satisfaction.

Proposal: one Safety Rope per attempt

A single recovery at step 4 reduces late-streak loss without removing the retry gate.

STREAK PROGRESS

SAFETY ROPE UNLOCKED

If the next level is lost:

The Safety Rope is consumed. The streak stays at 4, and the normal 30-minute retry wait still applies.

Design intent

Protect one late-stage attempt while preserving the seven-win goal and the time cost of failure.

EXPECTED BENEFIT

More players retry after a late loss

MAIN RISK

More winners may reduce the reward share and weaken the event's tension

A/B test and decision rule

The test should improve late-streak recovery without making the event trivial.

GROUP	EXPERIENCE	PURPOSE
Control	Current Swinging Bridge rules	Baseline
Test	One Safety Rope unlocked at step 4	Measure recovery from late loss

Primary metric

Retry rate after a loss at steps 4–6

Diagnostic metrics

Streak completion rate
Safety Rope activation
Time to next attempt

Guardrails

Winner count per group
Reward per winner
Booster use and revenue

Decision rule

Ship only if late-loss retries improve and the winner count, reward value, and monetization stay within agreed limits.
